Keywords: Statistics in the Social and Political Sciences, Corpus linguistics, Textometry, Textual data analysis

We present the TextometrieR package which aims at providing tools for texts and corpus analysis. The package originates in the french tradition of textometry, born after the Benzécri’s seminal works on multidimensional analysis (Lebart et al. 1998). This tradition has developed numerous methods for exploring and visualizing textual data. In the context of a growing interest for R in corpus linguistics (Gries 2008), this package add a new milestone after the packages zipfR (Hevert and Baroni, 2006) and languageR (Baayen, 2008).

The textometrieR package is developed as part of a research project gathering several representatives of this french tradition, including statisticians, linguists, scholars working on the historical, political or literary discourses, etc. This project aims at summing up the work done in textometry in the past decade. It will provide methods for exploring collocation between words (allowing to identify various phenomenon, from lexicalized multi-word units to stylistic/ideological association between words), building concordance, observing lexical distribution (growing of vocabulary, zipfian distribution) performing multifactorial analysis (for instance in texts typology, comparing diachronical or genre difference between texts, etc.).

From an architectural point of view, the textometrieR package is the statistical component of a platform which associates R and the IMS Open Corpus Workbench, a powerful full text indexer and search engine, under a single Java API. The R/Java communication is based on rJava. This platform provides a uniform environment to query plain text corpora or annotated corpora (i.e. containing metadata or linguistic annotations), in order to build quantitative structures such as frequency lists or contingency tables, and to benefit from R power to analyze and visualize those structures.
